## CLASS I, II & III CLASSIFICATIONS

The classification of warning lamps is meant to aide in the differentiation of lamps and output based on application and need. Some applications require brighter light output, while others require light output of a different direction or visibility.

Class I - The Class I lighting classification differentiates warning lights with the sole purpose of being used in applications in motion at the speed of traffic.

Class II - Class II lighting products are designed for vehicles that are in motion, but not to the speed of traffic.

Class III - Class III products are designed for products that are not in motion at all.

## FLASHES PER MINUTE

Flashes per minute, also noted as flashes per sequence, depicts the number of pulses or spikes a lamp generates within one minute of activity. Flashes per second are usually depicted as single flash, dual flash or quad flash, with the pulses being grouped together in series of flashes. A great benefit that SWL lamps provide is in their qualification of the flash being 100% accurate. With the quad flash of an SWL lamp, four flashes of equally high intensity are recorded prior to a separation gap. When gas discharge lamps generate their quad flash pattern, the first flash peaks at a level greater than that of the three following spikes, as the lamp needs to recover from its use of power in order to create the next large flash. All four flashes are not equal, but all can be "counted" equally in determining flashes per second or flashes per minute.

**Turn Signal Switches**      **200-202**

**Horns**      **203**

**Back-up Alarms**      **203-205**

**Flasher devices provide four primary functions:**

Flashes the signal lamps on and off when the turn signal switch is activated. Provides outage indication (specific load flashers only) when a lamp is out of service. Causes the turn signal lamps to flash when the hazard warning switch is activated. Provides an audible sound indication when any signal device is activated. Alternating flashers provide the side to side flashing pattern required for emergency vehicles and school bus applications. "Fixed load" flashers are designed for a specific number of lamps and offer outage indication. "Variable load" flashers are designed for applications where the required load is not constant, such as when a tow vehicle is added or for vehicles pulling varying configurations of trailers. In order to determine your proper flasher requirements, engage the hazard warning switch and count the number of lamps that flash on both the primary power unit and trailer vehicle that unit may pull. The following chart will help you match your flasher load needs with your service requirements.

**HOW TO SELECT SIZE OF ELECTRIC CABLE**

Voltage drop is the primary consideration in selecting the proper electrical wire size. The length of wire in a circuit is the major contributing factor to voltage drop. The table below may be used in determining adequate wire gauge sizes for specific lengths of cable when the amperage requirements are known.

Example: A lamp is 38 ft. from the power source and requires 10 amperes. This figure, when rounded upwards to the nearest column heading given in the table, is 40 ft. The wire gauge in the "40-ft. Column" corresponding to 10 amperes is No. 12.

\*It is recommended to balance the circuits as practicable.

Note: This table gives you the resistance of wire per foot so with ohms law V=I x R you can calculate voltage drops on any of the above wire gauges at any current level and length. For example, voltage drop in 50 ft. 10 AWG wire with 20 amp load is V=20 amp x (0.00103 Ω /ft.) x 50 ft. = 1.03 volts. Be sure to include both the positive and negative leads when calculating total wire length.
